## BEES FROM EAST GIPPSLAND. <br> By Tarlton Riyment.

Mr 1. Clark, of the Natipnal Muscum, Melbounne, has been kind enongh to allow me the privilege of stadying the bees that he collected when visiling East Gippsland, AII of the honey-gathereis wexe working on the flowers of a Leptospormum. I was not, at all surprised to find that the species waried from the type-forms, bectuse the flora of the extreme eastern end of the State is pectilar, and the olimatic conditions are, in sbme ways, unique. The Red-bees, of the genas Bioghamielha, are so dark that I feel gustified in referring them to a new variety. The Fowhetus, the Parasphecodes and the Gnathoprosopis are new.

## DIVISION COLLETIFORMES. <br> Family Prosopididae

Bingbamelda antupodes (Simith), variety mgro, a, var
This form is sightly smaller than Smitli's type, and thongh the rentarkable seulptiring of the metathorax presents no strictural differences, the red of the abdomen is indefinite. The first segment is jet-black and highly polishod, and the other segments aro so strongly suffused with black that the red is very obscure. Moreover, the wings, too, are mull more strongly coloured with the purplish black iridescence. Specimens of this gentrs from Crovdon, Ringwood, Ferntree Gully and Kiala have a clear-ted abdomen, with only portion of the first segment showing any black, but these Cann River temales are dark enough to be called mogra, A specimen from West Australia (Forst) bas no black on the abdomen. Type in National Mosenim, Melbourne.

Grishopacosopis nigrtadrses, n. sp.
Femble-Lprigth, bmm. upprox. Head Black, ondinary. Face-marlss lemon-yellow, pointed helow, wary trunate at insertion of antennae; frons closely and fincly puncturod, dull; dypens panctived, but not so olosely as frons; supiaelypeal area smilin to foont, vertex with wine pink ocelliz compound eycs claret-brown, slightly eonverging below; gense witli fine striation; labrum black; mandibulae truncate, bidentate, hackish-brawns anternae mumoniliform, seape black, slightly dilated, Aagellum black above, ferruginum beneath. Prothorax swollen laterally, lemon-yellow, exeept fine black interruption at middle. Tubercles bright jemon-yellow. Mesothorax dull, back; finely and closely punctured, nimute lines joining the punctures. Scutellmm similar to mesthorax. Postsentellom similar to mesothorax. Mictathoras black, bright, with rugae, ipartly' radiating, of medimut size.' 'An-
domen = dorsal segments blaek, bright, alosely punctured, but not so close as on mesothorax; ventral scrments blach, with a few short stifl white hairs. Legs black, with a few short stiff white hairs. Tarsi black, anterior and middle wits fulvout hairs; claws blackish-red; hand calcariae pale, finely serrated. Tcgnlae lilack, bright, with the seulpture of the mesothorax. Wings hyaline jridescent; nervüres hlackish-brown, basal areked, just short of nervulus, second interenbilns bent; cells: radial large, second guhital receiviug second rechrent at apical third; pterostigma large, blackish-brow't; bamuli five ${ }_{r}$ of weak development.

Locality, Cann River, Gimpshand, Vietmia, Date, November, 1928.

Biological data: On flowers of a Laphospermmen. I have a specimen from flowers of Eucalyptus calophylla, at Sandringhan. This bee has a minute creamy spot at the base of the tibia, and lacks the tulvous hair of the tarsi. It may be regarded as variety maothato.

There is a large group of Australitu becs, about 6mm in leugth, with a briglat yollow collar on prothorax, yellow facemarks and finbekcles, and with yellow on the legs.

Guathoprosapis hueckert, Ckll, has scapes with a reddish stripe; vellony of Icgs, ard light markings on posterior tibiae. Gnathoprosopis nigritarsts, Raym, legs entirely black the tegulae black. (fomothoprosopis nigritarsus var maculata, Raym., yeliow on legs confined to a creamy spot at base of tibia.

> DIVISTON ANDRENIFORMES. Family Andrenidac. Subfamily Halictinge. Hatictue mictosty, n . sp.

Female-I Iengtl, 8.smm, approx. Face-maxks nil, fuons coarsely punctured, a fus seattered white hairs. Olypeus prominent, eoassely puretired. Suprablypeal area coarsely nunctured, hright, a fery white hairs. Vertex with clear glassy orelli. Compoind eyes elaretbrown. Genae puncimed, a few white hairs; Jalnom black mandibulae blorlh, with obscure rufous patch; antennae black, siibmoniliform. Prothorax not visible from above; tubercles black, a fringe of pale hair. Mesothorax black, coarsely and densely punctured, a few white hairs surround the thorax sentellum bi-qibbous; postscutellom, with a light covering of fulvous hair. Metathorax with a laxge, crescent-shaped area, with coarce anastomosing rugae diminisking at, sides of truncation. Abdemen dorsal segments shining hind margins very mairowly reddish, thita ritb at shining narow band of cimerernis pobescente, a patch
of similar hair at side. of second; ventral segments have a fringe of white hair. Legs black, with white hair, except the fulvous hair of the tibiae; tarsi with Tight futvons hair; claws pale reddish. Hind calcariae pale yellowish, with no defined teeth, but has a wide wayy edge. Tegolae darls amber Wings lryaliue; nervures dark amber; cells normal for Hatietus; pterostigma dark amber. Hamoli of moderate development.

Locality, Cann River, Gippsland. Date, November, 1928.
Biological data. Gaptured on Alowers' of a Leptospernam. At the request of Mr, A. Clark, 1 have dedicated the species to Senator R. D. Elliott.

This species is close to $H$. lamarius, Smith, and II. lanuphososts. Comparing it with a specimen of the former species determined by Prof. Cockerell, A. aftiotio is hacker, since it is less hairy; there is not any fulvous or light hair aboat the

1. Calcarise of thatiatus lonapzos Smirs, with peuble wedged by tooth.
2. Calcariae of Halicius elliothiz Rayment.
3. Fine sesrations highly magnified to show position of pollengranules.
rima; the margins of the segments are much more namowly reddish; lunar area of metathorax much better defined; tugulae lighter; pterostigma darker; anastomosing rugae of $H$, Allotii diminishes at sides, that of $H$, lanarins is coarse thronghont. The hind spar of $H$. lapariks has one prominent rounded tooth, and a wavy edge diminishing to the point; tarsi darker.

On many specimens of bees I have noted the fine serrations holding pollen gramles, and, since a minote examination reveals some relationship between the diameter of the granules and the size of the teeth, I suggest that one of the
spurs is used on the foral pollen-saes. The edarse teeth of the other spur are undoubtedly used for excayating soil, and 1 often find small pebbles redged tightly between the tooth and the spur. Trac exeavators of earth have coarse teeth on one spur, but those using shatts or cells made by others, have fiuc serrations on both calcariae. The Tonev-bee, Apis, has kist even the serrations, and bas only a simple smonth peg; of course, she has no digging to do. Male bees do nut excavats rand nome leas the cearse teeth on the calcariar

## Family Andrenidae. Subfamsly Hatictinae.

Parhspebeones firtiventris, Cockerell.
The type collected by Turner was deseribed fromi Araral, Victoria and the Cann River specimon is not quate typieal and perhals is an eastern race.

> Parasphecones rumbargus, nisp,

Fomale-Jeegth, J1mo appors. Head black, bright, facial guadrangle wider than long; faee-marks mill; a fine carina reaches more than half-way to median ocellus; frons slíning, coarsely and densely punctured, a few fulvous hairs radiating from bases of antennge; clypeus shining, protnincat, conarsely but sparsely punctured a fringe of golden hair on anterior edge; supraclypeal avea prominent, shining, coarsely but sparsely punctured; retes with nomerous finer punctures, a few fulvons hairs; compound eres backish, slighty converging below; genae slightly aeneas, well punctured, a few long whitish hairs: Jahrim black; mandibuae bisck, and strongly bent; antennae submonibiform, dark reddish. seape lighter at base and apex. Prothorsx is prominent with a Lunate thick eaft of deep cresm bair; mesothorax black, bright, well punctured, a few shoit falvons hairs; scutelhim sculptwed and colomed like mesothoras; postscutclimo rough, black, eovered with a scale-like pattern on which is superirnosed a striate seulphore too fine to be called rugac. Ahdrmen : dorsal segments, black, brjght, well punctured, numerous short, appressed black hairs, a few longer fulrous hairs at sides, a fow short cereamy haixe at hind margin of Second rima a bave reddish furow; ventral segments black. a light fringe of long white fair on margins Legs red, anterior femora and all covae black, apical ends of merlian and hind femors darker anterorly. with black hair, ntherwise the bail is pale. Tarsi dark rod, with fulwors hair. Claws blackish-red, putvilli luxge. Hind valcariae reddish-amber, with three short nodnliform teeth at apical end, of a form nearer to Nomix than Holoctus. Tegulae clear ferruginous. Wings dark, reddish-brown, carrang much fine black hair:
nervures veddish-black, basal, like fish-hook enrve, just shert of nervulus, first and second recurrents entering the cubital cells just short of the second and third intereubitus; cells: radial large, radius nevvure rounded on costa, second cubital cell narrowed at top. Pterostigma large, obscure reddishbrawn. Hammi thirteen in mumer, strongly developed.

Jocality, Cann River, Gippsland, Vietoria. Date, November, 1928.

Allies: the smaller P. plondor, Ckil., has black legs, and the sculptuse of the face is quite different. The spurs lack the eaarse tecth. Holicions franki, Frieses, also has some affinity, biat the first recurvent hervire meets the second intercubitns. II. Kitheri, CkIl., has white pubesemere at bases of seeond and thit lergites.

Biolngical data. This temale was collected Prom flowers of

1: Antenna-cleaner of female Parosphecodes nufitursus Rayment. Note the long, spined malus of Halictine form.
2. Hind spur or Celearia shows some sffrity to Nomia. The noduli-form teeth at tip are not typicsl of Halficus.
3. A lactoral viev of the apical end of spur.
4. Another view to show the twist of the end,
b. Metathorax showing position of the Strige-superimposed an in fine sculpture.
6. The peculiar scale-iike pattern of the integument highly magnified.
a Teptospermum, and the species is in the botder line of Halictns and Poraspheiodes; owing to the strusture of the medathorax and the caleariae, I have added it to the latter graus. Type in Melhomrne Museum.

> Family Andrenidae. Sublanily Nominac. Noma ghachipets, Smith.
This species has bem recorded from Victoria, Sonth Australia, and Queensiand, but I suspect there are blenty in New Sonth Wales, sinee Mr, Clark's Loeality is close to the border. The specimens from the Cant River have more hair, and are slighty larger than those recorded in the original
description; the hair of the legs being lighter: tlau, that on speosmens identified thy Prof. Cockerell.

> DIVISTON XYLOCOPIFORMES, Fanily Ceratinidac EXONETEA HAMMLAP, Cockecell.

Previonsly: yecorded from Queensland, where it was, col-lected-by Mr. Hacker. The Cann River females are typbal, with the exeeption of a iriangular black pateh on fivst segment, and since there is some variation in thes colour pateht, $I$ do not aftacle any importance to it.

Exoneuba concinnula, Caekerell.
Provimusy recorded from New South Wales. Botli these bees are now added to the Vjetorian Launa.
Nota bene: The specific descriptione bave been systematisel, and 1 shall wse this form for all fntave work, The nomonelatiare of the cells and nervures of the wings is based on the arbituary inctlod of Rohwer and Gahan (1916), Systems based no homologies with the veins in other mirdors are too cunbersome for use in tazonomy.

## Dfi, I. A. LEACH

Whe lafe Dr I A. Lefrich was elected a member of the Olub in Docembur, 1902, Fums yeurs later be was elected to the committec, and later was onse of the vice-presidente, boomuing presidenf in June. 1413. However. fuding his thomtmontal dities celled hitu 80 minch away fom Melbontio, the resigned the position affer- only - two montis occupmer, Mr. J. A. Kershaw hetng electod to fill the vocancy 712 Mmeh, 3904. Le tend a papor concembeg the \#nding of the Anuphelex anospuito in Vietorif. This farn helps to spread The malalial fever: of the tropics. but, wortunately; "m to the bresent. it seems to have had no effect on the lealth of Victoria... is
